

Assessment Schedule – 2017

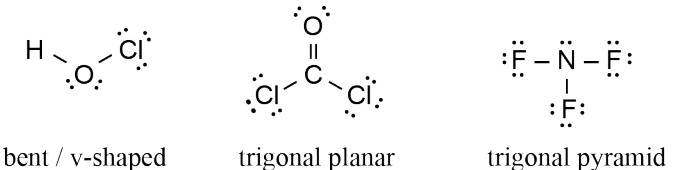

Chemistry: Demonstrate understanding of bonding, structure, properties and energy changes (91164)

Evidence Statement

Q	Evidence	Achievement	Merit	Excellence
ONE (a)	Exothermic The temperature increased / energy or heat has been released into the surroundings / energy is lost from the substance (CaCl ₂)	<ul style="list-style-type: none"> Correct term with reason. 		
(b)(i)	The water in sweat is changing state from liquid to gas. It needs to absorb energy to break the forces / bonds between liquid water molecules. It absorbs this from the heat of the body. The temperature of the body increases when exercising, so more water can be evaporated.	<ul style="list-style-type: none"> Identifies absorption of energy (or used) OR bonds breaking. 	<ul style="list-style-type: none"> Identifies the state change as bond breaking and EITHER link this to (heat) energy used / endothermic OR links to increased / faster evaporation due to increased heat from exercise. 	<ul style="list-style-type: none"> Full explanation including linking: state change to bond breaking with energy used / endothermic, and in turn to increased / faster evaporation due to increased heat from exercise AND correct enthalpy diagram with labels.
(ii)	 <p>Can show activation energy but not required.</p>	<ul style="list-style-type: none"> Diagram correctly drawn, but not labelled. 	<ul style="list-style-type: none"> Diagram correctly drawn and fully labelled. 	
(iii)	Sodium chloride is an ionic substance made up of Na ⁺ and Cl ⁻ ions arranged in a (3D) lattice and held together by ionic bonds. The δ- O of polar water molecules are attracted to the positive Na ⁺ , while water's δ+ H is attracted to the negative Cl ⁻ , this attraction is sufficiently strong to overcome the attractions between the ions in the salt / crystal / lattice (and between the water molecules in the solvent), dissolving the NaCl. See Appendix One for an example of labelled diagram.	<ul style="list-style-type: none"> Identifies that NaCl is ionic made up of Na⁺ and Cl⁻ ions. Identifies H₂O is polar / δ- O and δ+ H. 	<ul style="list-style-type: none"> Explains the attractions between polar water molecules and the two types of ion. 	<ul style="list-style-type: none"> Solubility of NaCl fully explained supported by a diagram(s) showing the correct arrangement of water and Na⁺ and Cl⁻, in terms of attractions.

(c)	$n(\text{Fe}_2\text{O}_3) = \frac{50.0 \text{ g}}{160 \text{ g mol}^{-1}} = 0.313 \text{ mol}$ $n(\text{CuO}) = \frac{50.0 \text{ g}}{79.6 \text{ g mol}^{-1}} = 0.628 \text{ mol}$ <p>Reaction 1: If 1 mole of Fe_2O_3 releases 852 kJ energy $0.313 \text{ mol} \times 852 \text{ kJ mol}^{-1} = 266 \text{ kJ}$ energy released</p> <p>Reaction 2: If 3 mole of CuO releases 1520 kJ energy Then 1 mole of CuO releases 507 kJ energy $0.628 \text{ mol} \times 507 \text{ kJ mol}^{-1} = 318 \text{ kJ}$ energy released</p> <p>So 50.0 g CuO releases more energy than 50.0 g Fe_2O_3 OR CuO releases more energy (52 kJ) than Fe_2O_3 OR Reaction 2 releases more energy.</p>	<ul style="list-style-type: none"> Amount (moles) of both Fe_2O_3 and CuO correct. 	<ul style="list-style-type: none"> Correctly calculates energy released for either Reaction 1 or Reaction 2. 	<ul style="list-style-type: none"> Both Fe_2O_3 and CuO calculations with units (kJ) are correct with appropriate significant figures, and a statement identifying CuO / Reaction 2 as releasing more energy.

Q	Evidence	Achievement	Merit	Excellence
TWO (a)(i)	 <p style="text-align: center;">bent / v-shaped trigonal planar trigonal pyramid</p>	<ul style="list-style-type: none"> Two Lewis structures (electron dot diagrams) correct <p>AND</p> <p>Two shapes correct.</p>		
(ii)	<p>Bond angle is determined by the number of electron density regions around the central atom, which are arranged into a position to minimise repulsion / are arranged as far apart from each other as possible (maximum separation).</p> <p>HOCl has 4 electron density regions / areas of negative charge around the central O atom. This means the electron density regions around the central atom is arranged with maximum separation in a tetrahedral shape with a bond angle of 109.5°, to minimise (electron-electron) repulsion. Due to the presence of two non-bonding pairs of electrons / regions (or two bonding regions) on the central O atom, HOCl has an actual shape that is bent / v-shaped / angular.</p> <p>COCl₂ has only 3 electron density regions / areas of negative charge around its central C atom so the electron density regions around the central atom is arranged with maximum separation in a trigonal planar shape with a bond angle of 120°, to minimise (electron-electron) repulsion. Since COCl₂ has only bonding electron pairs (no non-bonding pairs) on its central atom, the actual shape is trigonal planar (with bond angles of 120°).</p>	<ul style="list-style-type: none"> Identifies the numbers of electron density regions / electron clouds / regions of negative charge around the central atoms for ONE molecule. <p>OR</p> <p>Identifies non-bonding pairs and bonding pairs of electrons on the central atoms for ONE molecule.</p>	<ul style="list-style-type: none"> Links areas of negative charge around the central atom to minimise repulsion (maximum separation) and bond angle OR shape for ONE molecule. 	<ul style="list-style-type: none"> Justifies the correct bond angle and shapes of BOTH molecules by linking electron density regions around the central atom to bond angles and shape.
(b)(i)	<p>Dichloromethane is polar. Tetrachloromethane is non-polar.</p>	<ul style="list-style-type: none"> Identifies polarity of both molecules. 	<ul style="list-style-type: none"> Links bond polarity / or bond dipoles / atoms δ- and δ+ to electronegativity differences between bonded atoms for one molecule. <p>OR</p> <p>Uses symmetry / differing dipoles to link molecule polarity to dipoles cancelling / not cancelling for one molecule.</p>	<ul style="list-style-type: none"> Justifies polarity of dichloromethane and non-polarity of tetrachloromethane by referring to differences in electronegativity, dipoles, and symmetry of molecules.
(ii)	<p>In CCl₄, the four C–Cl bonds are polar, i.e. have a dipole, due to the difference in electronegativity between C and Cl. These (equally sized) dipoles are arranged in a symmetric tetrahedral shape, resulting in the dipoles / bond polarities cancelling each other out, so CCl₄ is non-polar.</p> <p>In CH₂Cl₂, there are two types of bond, C–H and C–Cl, each polar with dipoles due to the difference in electronegativity between C and H and C and Cl. These dipoles have different polarities / sizes as H and Cl have different electronegativities. (Despite the symmetric tetrahedral arrangement) the different (sized) dipoles / bond polarities do not cancel each other out, so CH₂Cl₂ is polar.</p>	<ul style="list-style-type: none"> Identifies that the atoms within the bonds have different electronegativities. <p>(For one type of bond)</p>		

(c)	<p>Reaction 1 Hydrazine and oxygen</p> <table border="0"> <tr> <td colspan="2">Bond breaking</td> <td colspan="2">Bond making</td> </tr> <tr> <td>N–N</td> <td>158</td> <td>N≡N</td> <td>945</td> </tr> <tr> <td>N–H × 4</td> <td>1564</td> <td>O–H × 4</td> <td><u>1852</u></td> </tr> <tr> <td>O=O</td> <td><u>498</u></td> <td></td> <td><u>2797</u></td> </tr> <tr> <td></td> <td>2220</td> <td></td> <td></td> </tr> </table> <p>Bond breaking – bond making 2220 – 2797 = –577 kJ mol⁻¹</p> <p>Reaction 2 Hydrazine and Fluorine</p> <table border="0"> <tr> <td>N–N</td> <td>158</td> <td>N≡N</td> <td>945</td> </tr> <tr> <td>N–H × 4</td> <td>1564</td> <td>H–F × 4</td> <td><u>2268</u></td> </tr> <tr> <td>F–F × 2</td> <td><u>318</u></td> <td></td> <td><u>3213</u></td> </tr> <tr> <td></td> <td>2040</td> <td></td> <td></td> </tr> </table> <p>Bond breaking – bond making 2040 – 3213 = –1173 kJ mol⁻¹ (or -1170 kJ mol⁻¹)</p> <p>Reaction 2 releases more energy than Reaction 1 (by 596 kJ mol⁻¹).</p>	Bond breaking		Bond making		N–N	158	N≡N	945	N–H × 4	1564	O–H × 4	<u>1852</u>	O=O	<u>498</u>		<u>2797</u>		2220			N–N	158	N≡N	945	N–H × 4	1564	H–F × 4	<u>2268</u>	F–F × 2	<u>318</u>		<u>3213</u>		2040			<ul style="list-style-type: none"> Identifies the bonds broken and bonds formed for both equations. <p>OR</p> <p>Correct process for one reaction.</p>	<ul style="list-style-type: none"> Correct process giving the correct answer for one reaction. 	<ul style="list-style-type: none"> Correct process and answers for both reactions, including correct units (kJ mol⁻¹), and states Reaction 2 releases more energy.

Solid	Type of solid	Type of particle	Attractive forces between particles																				
Al(s) (Aluminium)	<i>metal / metallic</i>	<i>atoms (or cations and delocalised valence electrons)</i>	<i>metallic (bonds)</i>																				
MgCl ₂ (s) (Magnesium chloride)	<i>ionic compound</i>	<i>ions</i>	<i>ionic (bonds)</i>																				
S ₈ (s) (Sulfur)	<i>molecular</i>	<i>molecules</i>	<i>intermolecular (bonds)</i>																				
(b)	<p>Sulfur has the lowest melting point.</p> <p>Sulfur is a molecular substance with weak intermolecular forces between the molecules. These forces do not require much energy to overcome, so they will break at lower temperatures, giving sulfur a lower melting point.</p> <p>Al is a metal with strong metallic bonds. These attractions require a lot of energy to overcome, so the melting point is higher than sulfur's melting point.</p> <p>MgCl₂ is an ionic compound with strong ionic bonds between the cations and anions. These bonds also require a lot of energy to overcome, so the melting point is also higher than sulfur's melting point.</p> <p><i>(Candidates are not expected to know whether Al or MgCl₂ has the higher melting point.)</i></p>				<ul style="list-style-type: none"> • Describes the attractive intermolecular forces as weak or requires a small amount of heat / energy to break for S₈. • Describes the attractive intermolecular forces as strong or requires a large amount of heat / energy to break for MgCl₂. • Describes the attractive intermolecular forces as strong or requires a large amount of heat / energy to break for Al. 	<ul style="list-style-type: none"> • Links the correct attractive forces / bonding strength to energy / heat requirements for TWO of the substances. 	<ul style="list-style-type: none"> • Justifies choice by linking the correct attractive forces / bonding strength for ALL three substances to energy requirements and in turn to melting point. 																
(c)	<p>Aluminium is malleable.</p> <p>Aluminium is a metal made up of atoms / cations in a sea of electrons which are held together by non-directional metallic bonds in a (3D) lattice. The metallic bonds are non-directional as the (bonding) electrons are delocalised across the lattice / shared by many atoms. When a force (or pressure) is applied the atoms / layers can move without breaking / disrupting these non-directional bonds thus the structure can change shape without breaking the lattice.</p>				<ul style="list-style-type: none"> • Identifies aluminium and describes bonding as non-directional. <p>OR</p> <p>Describes structure of aluminium (could be shown in a diagram) as a lattice.</p>	<ul style="list-style-type: none"> • Links malleability of aluminium to non-directional metallic bonding. <p>OR</p> <p>Links malleability of aluminium to layers / atoms able to move past each other with pressure / force or without breaking bonds.</p>	<ul style="list-style-type: none"> • Justifies choice with respect to structure and non-directional bonding for aluminium.
